

On the Rails side, the hikes controller didn't do anything special. If you look at the code, it looks pretty…well, boring. It just redirected to the show page!

ch03_08/rails/app/controllers/hikes_controller.rb

```
  class HikesController < ApplicationController
    def create
      @hike = Hike.new(hike_params)
      if @hike.save
»       redirect_to @hike, notice: "Hike added."
      else
        render :new, status: :unprocessable_entity
      end
    end
  end
```

Hotwire Native is smart enough to "catch" that redirect and render it in a new screen. And because the new hike route, `/hikes/:id`, doesn't have any special path configuration, the modal gets dismissed and the show page gets pushed on the main, non-modal stack.

There's another bonus we get with Hotwire Native related to forms. Submitting an invalid form renders the flash message with all of our errors, just like we expect on the web:
