Configure Tabs on iOS

Hotwire Native comes with first-party support for native tabs with `HotwireTabBarController`. To configure the tabs for your app, you'll have to do the following:

1. Create a model to manage the tabs.
2. Migrate from `Navigator` to `HotwireTabBarController`.

Manage Tabs with a Model

You'll keep track of the individual tabs in a model object. It will be responsible for configuring each tab's visual appearance and which URL to display from the server. Having this configuration in one place also means we can update a single file to change our tabs.

Get started by creating a new folder under `App` named `Models`. Then right-click the `Models` folder and select New File From Template….

Select the iOS tab at the top and Swift File under the Source section, and click Next.
