What’s Next?

You just learned how to create and configure a native tab bar on iOS and Android. For iOS, you picked up some knowledge about SF Symbols. And on Android, you learned how to work with multiple views in a single XML layout.

When developing apps with Hotwire Native, simply being aware of first-party components like `HotwireTabBarController` and `HotwireBottomNavigationController` can often save a lot of time. I’ve gone through many iterations of custom versions of native tab bars, but I’ll be sticking with the ones outlined in this chapter for a long time.

When it comes to interacting with native APIs in Hotwire Native apps, native tabs just scratch the surface. Next, we’ll explore how to further level up our app with completely native screens powered by SwiftUI on iOS and then Jetpack Compose on Android.
