Build a Native Screen with SwiftUI

For our Hiking Journal app, we're going to upgrade the web-based map screen to a native one powered by SwiftUI,[28] Apple's declarative framework for building user interfaces.

The next image is a before (left) and after (right) shot of what you'll build. It might not *look* much different, but interacting with the native map on the right will be a much better experience for your users. I mean, have you ever tried to pan or zoom a map on a mobile website? What a pain!

Adding our SwiftUI map screen to the Hotwire Native app requires a few steps:

1. Render a map with a SwiftUI view.
2. Connect the view to Hotwire Native with a view controller.
3. Route the URL via path configuration.
4. Expose a JSON endpoint for structured hike data.
5. Fetch and parse the JSON with a model and a view model.
