Connect to Hotwire Native with a View Controller

Under the `Controllers` folder, create a new Swift file named MapController. As usual, delete the contents. Then import both SwiftUI and UIKit.

Declare a `MapController` class but don't inherit from `UIViewController`. Instead, inherit from `UIHostingController<MapView>`.

ch05_03/ios/App/Controllers/MapController.swift

```
import SwiftUI
import UIKit

class MapController: UIHostingController<MapView> {
}
```

The UI framework we've been using up until now is called UIKit. Remember importing UIKit at the top of a few files in previous chapters? From experience, this framework aligns nicely with how Hotwire Native and Rails apps navigate between views. But our map view is built with SwiftUI, not UIKit. So we need a way to bridge the gap between the two frameworks.

`UIHostingController`[29] does exactly that. Each hosting controller needs to be *typed*—the class name between the angle brackets means that this controller renders a `MapView`.

Next, create a *convenience* initializer that accepts a `URL`. You'll use this later to determine which hike to render a map for. Inside the initializer, create a `MapView` and pass it to `self.init(rootView:)`.

ch05_04/ios/App/Controllers/MapController.swift

```
import SwiftUI
import UIKit
```
