Fetch and Parse JSON with a Model and a View Model

To make it easier to work with dynamic data, we can decode the JSON response into a concrete model. With the help of `Decodable`, you can parse this JSON with a single line of code.

Create a Model

Create a new Swift file in the Models folder and name it Hike. Inside, create a new struct with the properties from the JSON payload, conforming to the `Decodable` protocol.

ch05_11/ios/App/Models/Hike.swift

```
struct Hike: Decodable {
    let name: String
    let latitude: Double
    let longitude: Double
}
```

Remember how `Marker` in the view required a coordinate? To do this, create a computed property for `Hike` that exposes the latitude and longitude as a `CLLocationCoordinate2D`. Make sure to import the MapKit framework at the top, too:

ch05_12/ios/App/Models/Hike.swift

```
» import MapKit

struct Hike: Decodable {
    let name: String
    let latitude: Double
    let longitude: Double

»     var coordinate: CLLocationCoordinate2D {
»         CLLocationCoordinate2D(
```
