```
»             latitude: latitude,
»             longitude: longitude
»         )
»     }
  }
```

With the model in place, you need somewhere to kick off your network request and populate the view. In SwiftUI, these places are usually called *view models*—they bind data to UI elements and perform some work to get them loaded into the app.

Create a View Model

Unlike **MVC** in Rails, SwiftUI uses the **MVVM** pattern to coordinate code. **MVVM** stands for Model, View, View Model, and consists of the following:

- Models—The data objects, similar to a Rails model
- Views—Render content to the screen, similar to a Rails view
- View models—Coordinate data flow between the two, like a Rails controller

The view model you create for the app will be responsible for three things:

1. Building a URL to fetch the JSON
2. Fetching the JSON from the network
3. Parsing the JSON into a model

First, create a new folder named ViewModels and add a Swift file named HikeViewModel to it. Inside, delete the comments but leave the import statement. Declare a class to match the filename and add the `@Observable` keyword before it, like so:

ch05_13/ios/App/ViewModels/HikeViewModel.swift

```
import Foundation

@Observable class HikeViewModel {
}
```
