ch05_18/ios/App/Views/MapView.swift

```
    #Preview {
»       let url = URL(string: "https://example.com")!
»       let viewModel = HikeViewModel(url: url)
»       viewModel.hike = Hike(
»           name: "Mount Tabor",
»           latitude: 45.511881,
»           longitude: -122.595706
»       )
»       return MapView(viewModel: viewModel)
    }
```

We've passed in a dummy URL and reused the hardcoded name and coordinates from earlier. Note that the `return` keyword is now needed because `#Preview` is more than a single line of code. Try and run the project again.

Ugh, now Xcode is complaining somewhere else! Follow the build error by pressing ⌘ ' to navigate to `MapController`.

To fix this, like earlier, `MapView` needs an instance of the view model:

ch05_18/ios/App/Controllers/MapController.swift

```
    import SwiftUI
    import UIKit

    class MapController: UIHostingController<MapView> {
        convenience init(url: URL) {
»           let viewModel = HikeViewModel(url: url)
»           let view = MapView(viewModel: viewModel)
            self.init(rootView: view)
        }
    }
```

The project is building again, and Xcode is happy. Up next, you'll use the view model in the view to render the marker on the map.

Open `MapView.swift` and unwrap `hike` from the view model:
