```
»               await viewModel.fetchCoordinates()
»           }
        }
    }
```

`.task()` is a *modifier*, a way to apply changes to the view's appearance, behavior, or other properties—these are used extensively throughout SwiftUI. Here, the modifier runs whatever code is inside the curly braces when the view loads. Some modifiers add functionality like `.task()`, while others can change the way a view is rendered, like changing the background color with `.background()`.

Run the app and visit the map again. It now renders each hike's coordinates and name dynamically.

You now have a map with all the touch, drag, and swipe affordances expected from a native app…but I think we can make it look even better.

Back in `MapView.swift`, add these `Map` modifiers to render a map that doesn't bleed into the navigation or tab bar and looks way more realistic:
