```
    struct MapView: View {
        var viewModel: HikeViewModel

        var body: some View {
            Map {
                if let hike = viewModel.hike {
                    Marker(hike.name, coordinate: hike.coordinate)
                }
            }
»           .mapStyle(.hybrid(elevation: .realistic))
»           .navigationTitle("Map")
»           .clipped()
            .task {
                await viewModel.fetchCoordinates()
            }
        }
    }
```

This gives us a beautiful rendering, as shown in the screenshot, which is much better than what we had before on the web.

And now, you have a dynamic map on iOS!

As you just learned, integrating a native screen requires a bit of coordination. First, you created a SwiftUI view that gets rendered via a
