Integrate Jetpack Compose with Hotwire Native

We'll convert our web-based map on Android using Jetpack Compose,[31] Android's declarative UI framework. We'll follow an approach similar to that used with iOS, but with a few extra configuration steps:

1. Build a Jetpack Compose screen.
2. Route the URL via path configuration.
3. Configure Google Maps with an API key.
4. Add a map to the view.
5. Fetch and parse the JSON with a model and a view model.

Before we dive in, there's one step of cleanup. Remember how we configured Hotwire Native in `MainActivity` in *Update the Activity*. On Android, we can put this Kotlin-powered configuration into a subclass of `Application`. This code runs when the app is launched—perfect for setting up Hotwire Native.

First, next to the `activities` and `models` packages, create a new Kotlin file named `HikingJournalApplication.kt` that subclasses `Application`.

ch06_01/android/app/src/main/java/com/masilotti/hikingjournal/HikingJournalApplication.kt

```
package com.masilotti.hikingjournal

import android.app.Application

class HikingJournalApplication : Application() {
    override fun onCreate() {
        super.onCreate()
    }
}
```

Tell Android where this lives by setting `android:name` in `AndroidManifest.xml`. Note the leading dot!
