Fetch and Parse JSON with Model and View Model

As expected, we'll model our approach on what we did for iOS. Start by creating a new Kotlin Data class under the `models` package named `Hike.kt`. Add an attribute for `name`, `latitude`, and `longitude`.

ch06_20/android/app/src/main/java/com/masilotti/hikingjournal/models/Hike.kt

```
package com.masilotti.hikingjournal.models

data class Hike(
    val name: String,
    val latitude: Double,
    val longitude: Double
)
```

Then, expose the coordinate via a computed property. We'll use this to initialize the `LatLng` when positioning the map.

ch06_21/android/app/src/main/java/com/masilotti/hikingjournal/models/Hike.kt

```
  package com.masilotti.hikingjournal.models

» import com.google.android.gms.maps.model.LatLng

  data class Hike(
      val name: String,
      val latitude: Double,
      val longitude: Double
» ) {
»     val coordinate: LatLng
»         get() = LatLng(latitude, longitude)
» }
```

Continuing our mental model from iOS, we'll use a view model to fetch data from our server and populate the model.
