The `@Composable` function at the bottom of the file exists on its own—it's not a part of `MapFragment`. For it to use the view model, we need to pass a reference along when invoked.

ch06_28/android/app/src/main/java/com/masilotti/hikingjournal/fragments/MapFragment.kt

```
    // ...

    @HotwireDestinationDeepLink(uri = "hotwire://fragment/map")
    class MapFragment : HotwireFragment() {
        private lateinit var viewModel: HikeViewModel

        override fun onCreateView(
            inflater: LayoutInflater,
            container: ViewGroup?,
            savedInstanceState: Bundle?
        ): View {
            viewModel = HikeViewModel(url = "${navigator.location}.json")

            val view = inflater.inflate(R.layout.fragment_map, container, false)
            view.findViewById<ComposeView>(R.id.compose_view).apply {
                setContent {
»                   MapView(viewModel = viewModel)
                }
            }
            return view
        }
    }

    @Composable
»   fun MapView(viewModel: HikeViewModel) {
        // ...
    }
```

Now, we can change the hardcoded marker, camera, and title values to the ones retrieved from the view model.

ch06_29/android/app/src/main/java/com/masilotti/hikingjournal/fragments/MapFragment.kt

```
    // ...
```
