Create a Stimulus Controller

Next, create a new Stimulus controller by running the following command from the `rails` directory:

```
bin/rails generate stimulus bridge/button
```

This creates a new file at `app/javascript/controllers/bridge/button_controller.js`. Remember, the nested `bridge` directory helps us separate web-only Stimulus controllers from bridge components.

Open the controller and replace the import statements with those from the newly added JavaScript library. Also, change the base class to `BridgeComponent`.

ch07_03/rails/app/javascript/controllers/bridge/button_controller.js

```
» import { BridgeComponent } from "@hotwired/hotwire-native-bridge"

» export default class extends BridgeComponent {
  }
```

Next, set the component's identifier to "button". You'll do the same in the native component, the common name wiring the two pieces together.

ch07_04/rails/app/javascript/controllers/bridge/button_controller.js

```
  import { BridgeComponent } from "@hotwired/hotwire-native-bridge"

  export default class extends BridgeComponent {
»   static component = "button"
  }
```

As with most Stimulus controllers, we'll do our configuration in `connect()`. Add this function and don't forget to call `super`—`BridgeComponent` is an extension of a Stimulus controller, after all.
