```
            [UIApplication.LaunchOptionsKey: Any]?
        ) -> Bool {
            Hotwire.loadPathConfiguration(from: [
                .server(baseURL.appending(path: "configurations/ios_v1.json"))
            ])

»           Hotwire.registerBridgeComponents([
»               ButtonComponent.self
»           ])

            return true
        }
    }
```

Under the hood, this appends `bridge-components: ["button"]` to the user agent of requests coming from the app. The Hotwire Native Bridge uses this string to identify which components an app supports. `connect()` won't be called for a component that isn't registered in the user agent, like on mobile web. But more on that later.

Back in `ButtonComponent.swift`, add an empty function to start receiving messages. Every time `send()` is called from the Stimulus controller on the web, `onReceive(message:)` gets called on iOS.

ch07_10/ios/App/Components/ButtonComponent.swift

```
    import HotwireNative
    import UIKit

    class ButtonComponent: BridgeComponent {
        override class var name: String { "button" }

»       override func onReceive(message: Message) {
»       }
    }
```

A quick way to validate that this is working is to add a static button to the screen. Inside of `onReceive(message:)`, add a native navigation bar button item. We'll make this button text dynamic later in the chapter.
