`ButtonComponent.MessageData`.

The `struct` itself implements the `Decodable` protocol, enabling JSON deserialization. This is perfect because the JavaScript sent from our Stimulus controller comes in as JSON. Inside the `struct`, there's a single `String` property: the title of the button.

Inside of `onReceive(message:)`, create an instance of `MessageData` by calling `data()` on `Message`. Then, pass that along to the `UIAction` to set the title of the button:

ch07_15/ios/App/Components/ButtonComponent.swift

```
    import HotwireNative
    import UIKit

    class ButtonComponent: BridgeComponent {
        override class var name: String { "button" }

        override func onReceive(message: Message) {
»           guard let data: MessageData = message.data() else { return }

»           let action = UIAction(title: data.title) { _ in
                self.reply(to: message.event)
            }
            let button = UIBarButtonItem(primaryAction: action)

            let viewController = delegate?.destination as? UIViewController
            viewController?.navigationItem.rightBarButtonItem = button
        }
    }

    private extension ButtonComponent {
        struct MessageData: Decodable {
            let title: String
        }
    }
```

The `guard` statement ensures that, if the JSON deserialization fails, the function will return early and not add a native button.
