With your serializer configured, you can now set up a `data class` to serialize. This will map the JSON payload to a Kotlin object that you can then read in your code.

Back in `ButtonComponent`, create a `MessageData` class that parses "title" to a `String` value.

ch08_16/android/app/src/main/java/com/masilotti/hikingjournal/components/ButtonComponent.kt

```
    // ...
    import dev.hotwire.navigation.destinations.HotwireDestination
    import dev.hotwire.navigation.fragments.HotwireFragment
»   import kotlinx.serialization.SerialName
»   import kotlinx.serialization.Serializable

    class ButtonComponent(
        name: String,
        private val bridgeDelegate: BridgeDelegate<HotwireDestination>
    ) : BridgeComponent<HotwireDestination>(name, bridgeDelegate) {
        // ...
    }

    @Composable
    private fun ToolbarButton(title: String, onClick: () -> Unit) {
        // ...
    }

»   @Serializable
»   data class MessageData(
»       @SerialName("title") val title: String
»   )
```

Then, extract data from the `Message` at the top of `addButton(message: Message)`, passing the `title` to the constructor of `ToolbarButton`.
