```
class ButtonComponent(
    name: String,
    private val bridgeDelegate: BridgeDelegate<HotwireDestination>
) : BridgeComponent<HotwireDestination>(name, bridgeDelegate) {
    // ...

    private fun addButton(message: Message) {
»       val data = message.data<MessageData>() ?: return

        val composeView = ComposeView(fragment.requireContext()).apply {
            id = buttonId
            setContent {
                ToolbarButton(
»                   title = data.title,
                    onClick = { replyTo(message.event) }
                )
            }
        }
        // ...
    }
    // ...
}
// ...
```

Here the `?:` operator, or the Elvis Operator,[49] only calls `return` if `message.data<MessageData>()` returns `null`. This is Kotlin's equivalent of a `guard` statement like you used on iOS.

Run the app and sign in. You'll see the Add and Save buttons correctly labeled, pulling in dynamic data that you set in the HTML in the previous chapter.
