```
            data: {
              controller: "bridge--button",
              bridge_title: "Edit",
              bridge_ios_image_name: "pencil",
»             bridge_android_icon_name: "edit"
            } do %>
            <i class="bi bi-pencil"></i>
            Edit
          <% end %>
        <% end %>
      </div>
    </div>

    <%# ... %>
  </div>
```

Next, you'll extract this new value and use it to set an icon on the button.

Remember how in *Add a Dynamic Image*, you sent a `String` directly to `UIImage(systemName:)` and iOS turned it into an image from SF Symbols? Well, we can't do exactly that on Android. Image resources on Android need to be statically bundled with the app—anything we want to use needs to be shipped when we deploy. Since there's no SF Symbols equivalent on Android, we'll bundle a custom font that includes all of the available Material Symbols. Kind of like a sprite sheet in game development!

Head to the Google Fonts icons page[50] to download the font. Make sure Material Symbols (new) is selected on the left. Then, scroll through the options at the top to the right and click Download Material Symbols.
