Production Server

Be aware that your iOS device must be on the same network as your Mac for this to work. But you can use the same technique when you deploy to a real production server: replace your machine's IP address with the full URL of your website. And if you want to get fancy, you could use an Xcode build configuration file[64] to set up your URLs.

With your iOS app deployed to TestFlight, let's move on to Android. To deploy the app to Android with Play Testing, you'll work through these steps:

1. Set up your app in the Google Play Console.
2. Generate a signed app bundle in Android Studio.
3. Distribute the build to testers.
