What's Next?

In this chapter, you learned how to deploy your app to real-world, physical devices with App Store Connect and the Google Play Console. Both platforms required minor code changes to use a different `baseURL` when built for distribution. On iOS, we hardcoded an `#if DEBUG` statement, and on Android we used a build variant for release builds. You also learned how to correctly code sign your apps for Apple and Google to verify that you did indeed build them.

So far, you've only invited yourself to the two releases. Try adding a second or third tester from App Store Connect and the Play Console. Gather feedback on your app from a larger group! Just make sure they are on the same network as your Mac and you keep your server running. Or, deploy the Rails app somewhere online and update `baseURL`—then your app will be accessible to anyone, anywhere.

Submit to the App Stores

Submitting your apps to the App Store and Google Play is only a few more steps. But there's nothing special needed for Hotwire Native apps. You can follow along with Apple's guide for the App Store[73] and Google's guide for Google Play.[74]

Now that you have the apps registered with Apple and Google, you can start integrating with their services, like push notifications. In the next and final chapter, you'll learn how to configure, register for, and send push notifications when someone likes a hike.
