

The Hotwire Native package is now integrated. So, let's get something on the screen!

Get the iOS App Running

Double-click `SceneDelegate` from the Project Navigator to open this file in the *editor area* in the center of the screen. This pane is where you'll write Swift code and where you'll spend most of your time in Xcode.

Apple provides a bunch of boilerplate code with new projects. But it assumes you're building a more traditional native app, not a hybrid one. So, for the Hotwire Native developer, this boilerplate code isn't that useful. Start by deleting the contents of the file. Yep, everything! You'll build up what you need, and only what you need, one line at a time.

A heads-up that I'll refer to files without their extension moving forward, for example, `SceneDelegate.swift`. But Xcode won't show the extension in the Project Navigator until you edit the filename.

Import Frameworks

Swift files have access to the Swift standard library and all code in the current package, your Xcode project. If you're referencing other code, then it needs to be imported. `SceneDelegate` uses the UIKit framework for building
