Did You Skip the Previous Chapter?

If you skipped Chapter 9, *Deploy to Physical Devices with TestFlight and Play Testing*, you'll need to register your app with Apple to be able to send iOS notifications via APNs. Work through all of *Add an App to App Store Connect*, to get yours set up.

Create a Bridge Component

The bridge component will tell the apps it's time to ask the user for permission to send notifications. First, generate a new Stimulus controller by running the following in the `rails` directory:

```
bin/rails generate stimulus bridge/notification_token
```

Replace the import statement and parent class to convert the Stimulus controller to a bridge component.

ch10_01/rails/app/javascript/controllers/bridge/notification_token_controller.js

```
import { BridgeComponent } from "@hotwired/hotwire-native-bridge"

export default class extends BridgeComponent {
}
```

Then, identify the component as "notification-token".

ch10_02/rails/app/javascript/controllers/bridge/notification_token_controller.js

```
import { BridgeComponent } from "@hotwired/hotwire-native-bridge"

export default class extends BridgeComponent {
  static component = "notification-token"
}
```

Wrap up this file by firing the "connect" message via `send()` when the controller connects.
