ch10_03/rails/app/javascript/controllers/bridge/notification_token_controller.js

```
  import { BridgeComponent } from "@hotwired/hotwire-native-bridge"

  export default class extends BridgeComponent {
    static component = "notification-token"

»   connect() {
»     super.connect()
»     this.send("connect")
»   }
  }
```

Wire up the controller by adding a `data-controller` to the hikes index page, wrapped inside of `user_signed_in?`. By using a bridge component, we can use Ruby to determine if the user is signed in and avoid any authentication logic in the native apps.

ch10_04/rails/app/views/hikes/index.html.erb

```
  <%= render "shared/header", title: "Hikes" %>

» <% if user_signed_in? %>
»   <meta data-controller="bridge--notification-token">
» <% end %>

  <% if @hikes.any? %>
    <div class="container list-group list-group-flush px-0">
      <%= render @hikes %>
    </div>
  <% else %>
    <p class="container">No hikes, yet.</p>
  <% end %>

  <%# ... %>
```

When the user accepts the triggered system dialog, you'll POST the notification token to your server. You'll come back and implement that code in the iOS and the Android sections later in the chapter. Right now, you're
