```
  class User < ApplicationRecord
    has_secure_password

    has_many :hikes
    has_many :hike_likes
    has_many :liked_hikes, through: :hike_likes, source: :hike
»   has_many :notification_tokens

    validates :name, presence: true
    validates :email, presence: true, uniqueness: true

    normalizes :email, with: -> { _1.strip.downcase }
  end
```

To get the token into the database, we need an endpoint for the apps to POST to. Up next, we'll create a new route and controller to register the notification token.

Add a Route and Controller

Add a new entry to `routes.rb` to create a new route for creating notification tokens.

ch10_08/rails/config/routes.rb

```
  Rails.application.routes.draw do
    resource :session, only: %i[new create destroy]

    resources :hikes do
      resource :map, only: :show
      resources :likes, only: %w[create destroy]
    end

    resources :users, only: :index do
      resources :hikes, only: :index, controller: :user_hikes
    end

»   resources :notification_tokens, only: :create

    resources :configurations, only: [] do
      get :ios_v1, on: :collection
      get :android_v1, on: :collection
```
