Configure iOS for Push Notifications

To configure iOS for push notifications, our path will mirror what we did in Rails:

1. Create a bridge component to authorize the sending of notifications.
2. POST the token to `/notification_tokens` from a view model.
3. Pass the token from `AppDelegate` to the view model.
4. Configure entitlements for push notifications.
5. Route, or deep-link, notifications.

Create an iOS Bridge Component

Start by creating a new bridge component under the `Components` folder named `NotificationTokenComponent`. Identify this the same as the one on the web, "notification-token."

ch10_22/ios/App/Components/NotificationTokenComponent.swift

```
import HotwireNative
import UIKit

class NotificationTokenComponent: BridgeComponent {
    override class var name: String { "notification-token" }
}
```

Just as in Chapter 7, *Build iOS Bridge Components with Swift*, you'll use `onReceive(message:)` to handle incoming messages.

Add this and call a new private function to request notification permissions.

ch10_23/ios/App/Components/NotificationTokenComponent.swift

```
import HotwireNative
import UIKit

class NotificationTokenComponent: BridgeComponent {
    override class var name: String { "notification-token" }
```
