```
»       override func onReceive(message: Message) {
»           Task { await requestNotificationPermission() }
»       }
»
»       private func requestNotificationPermission() async {
»       }
    }
```

The upcoming code to authorize notifications is an asynchronous operation, hence the `async` keyword on `requestNotificationPermission()`. Combined with `Task { await ... }`, we can pop off of the current thread and perform the task. We used a similar technique in `MapView` when we called `viewModel.fetchCoordinates()`.

Inside of the new function, request notification authorization for the following three options: alerts, sounds, and badges. If the user accepts, register for notifications via the shared `UIApplication` instance.

ch10_24/ios/App/Components/NotificationTokenComponent.swift

```
    import HotwireNative
    import UIKit

    class NotificationTokenComponent: BridgeComponent {
        override class var name: String { "notification-token" }

        override func onReceive(message: Message) {
            Task { await requestNotificationPermission() }
        }

        private func requestNotificationPermission() async {
»           let center = UNUserNotificationCenter.current()
»           let options: UNAuthorizationOptions = [.alert, .sound, .badge]
»           if try await center.requestAuthorization(options: options) {
»               UIApplication.shared.registerForRemoteNotifications()
»           }
        }
    }
```
