These three options are the most common combination when sending a notification on iOS. Check out the documentation[82] for the full list of notification options.

To address the compilation error, wrap the entire body of the function in a `do`/`catch` block, printing any runtime errors that occur.

ch10_25/ios/App/Components/NotificationTokenComponent.swift

```
    import HotwireNative
    import UIKit

    class NotificationTokenComponent: BridgeComponent {
        override class var name: String { "notification-token" }

        override func onReceive(message: Message) {
            Task { await requestNotificationPermission() }
        }

        private func requestNotificationPermission() async {
»           do {
                let center = UNUserNotificationCenter.current()
                let options: UNAuthorizationOptions = [.alert, .sound, .badge]
                if try await center.requestAuthorization(options: options) {
                    UIApplication.shared.registerForRemoteNotifications()
                }
»           } catch {
»               print("Failed to authorize: \(error.localizedDescription)")
»           }
        }
    }
```

That's all for the bridge component. Now, when `data--bridge--notification-token` appears in the HTML, the user will be prompted to receive push notifications.

Make sure Hotwire Native is aware of the component by registering it in `AppDelegate`.

ch10_26/ios/App/Delegates/AppDelegate.swift
