```
»           didRegisterForRemoteNotificationsWithDeviceToken deviceToken: Data
»       ) {
»           // POST token to server.
»       }
    }
```

While we're here, also add the function when registering that a token fails.

ch10_28/ios/App/Delegates/AppDelegate.swift

```
    import HotwireNative
    import UIKit

    @main
    class AppDelegate: UIResponder, UIApplicationDelegate {
        func application(
            _ application: UIApplication,
            didFinishLaunchingWithOptions launchOptions:
            [UIApplication.LaunchOptionsKey: Any]?
        ) -> Bool {
            // ...
        }

        func application(
            _ application: UIApplication,
            didRegisterForRemoteNotificationsWithDeviceToken deviceToken: Data
        ) {
            // POST token to server.
        }

»       func application(
»           _ application: UIApplication,
»           didFailToRegisterForRemoteNotificationsWithError error: any Error
»       ) {
»           print("Failed to register token: \(error.localizedDescription)")
»       }
    }
```

To get the `deviceToken` off of the device and onto your server, you need to make an HTTP request. Following the pattern we used in `HikeViewModel` from *Create a View Model*, you'll create another view model to do the same.
