POST the iOS Token from a View Model

Create a new file under `ViewModels` and name it `NotificationTokenViewModel`. Add an empty `async` function to register a token.

ch10_29/ios/App/ViewModels/NotificationTokenViewModel.swift

```
import Foundation

class NotificationTokenViewModel {
    func register(_ token: String) async {
    }
}
```

Next, build a `URLRequest` pointing to the `/notification_tokens` route you created on the server earlier. Set the HTTP method to POST and the required headers for the Rails app to parse the incoming payload as JSON.

ch10_30/ios/App/ViewModels/NotificationTokenViewModel.swift

```
import Foundation

class NotificationTokenViewModel {
    func register(_ token: String) async {
»       let url = baseURL.appending(path: "notification_tokens")
»
»       var req = URLRequest(url: url)
»       req.httpMethod = "POST"
»       req.setValue("application/json", forHTTPHeaderField: "Accept")
»       req.setValue("application/json", forHTTPHeaderField: "Content-Type")
    }
}
```

We'll encode the notification token in an `Encodable`, similar to what we did for `Hike` in `HikeViewModel`.

Create a new file under `Models` and name it `NotificationToken.swift`. Inside, create a `struct` that holds a `token` and a `platform`. The `platform` matches the validation we added to the `notification_token.rb` record on the server.
