Where's the Cookie?

On the Rails endpoint, we're using `current_user` to authenticate the user via a cookie. But we didn't do anything with cookies in the native HTTP request on iOS. So, where does it come from?

Hotwire Native iOS takes care of this for us automatically. After every web request completes successfully, each cookie is copied over from the web view to the cookie jar used for native HTTP requests.

Here's what that code looks like from Hotwire Native iOS:

```
// hotwire-native-ios:Source/Turbo/Navigator/Navigator.swift

extension Navigator: SessionDelegate {
    public func sessionDidFinishRequest(_ session: Session) {
        guard let url = session.activeVisitable?.visitableURL
        else { return }

        let store = WKWebsiteDataStore.default
().httpCookieStore
        store.getAllCookies { cookies in
            HTTPCookieStorage.shared.setCookies(
                cookies,
                for: url,
                mainDocumentURL: url
            )
        }
    }
}
```

The view model can now send a `String` token to the server. We only need a way to get the token to `register(_:)`. Remember that function we left empty in `AppDelegate`? We'll address that next.

Pass the Token from AppDelegate
