Open `AppDelegate` and create a private instance property for the view model. Then, from the empty function, pass `deviceToken` to the view model. Don't forget to wrap the call with `Task { await ... }` since the view model function, `register(_:)`, is marked with `async`.

ch10_34/ios/App/Delegates/AppDelegate.swift

```
    // ...

    @main
    class AppDelegate: UIResponder, UIApplicationDelegate {
»       private let viewModel = NotificationTokenViewModel()

        func application(
            _ application: UIApplication,
            didFinishLaunchingWithOptions launchOptions:
            [UIApplication.LaunchOptionsKey: Any]?
        ) -> Bool {
            // ...
        }

        func application(
            _ application: UIApplication,
            didRegisterForRemoteNotificationsWithDeviceToken deviceToken: Data
        ) {
»           Task { await viewModel.register(deviceToken) }
        }

        // ...
    }
```

Unfortunately, Xcode isn't happy. `deviceToken` is coming in as `Data`, but our function accepts a `String`:

> Cannot convert value of type 'Data' to expected argument type 'String'

Device tokens come from APNs as binary data for performance reasons.[83] To convert it to a `String`, we can map over each character, format it, and then join everything back to a single string.
