```
        }
    }
```

Initializing `NotificationRouter` with a reference to a `NavigationHandler` means you can pass along the notification's URL to have it visited with a new screen.

ch10_41/ios/App/Models/NotificationRouter.swift

```
import HotwireNative
import UserNotifications

class NotificationRouter: NSObject, UNUserNotificationCenterDelegate {
    private unowned let navigationHandler: NavigationHandler

    init(navigationHandler: NavigationHandler) {
        self.navigationHandler = navigationHandler
    }

    @MainActor
    func userNotificationCenter(
        _ center: UNUserNotificationCenter,
        didReceive response: UNNotificationResponse
    ) async {
        let userInfo = response.notification.request.content.userInfo
        if let path = userInfo["path"] as? String {
            let url = baseURL.appending(path: path)
            navigationHandler.route(url)
        }
    }
}
```

Next, we need something to conform to the `NavigationHandler` protocol. Turns out that those Hotwire Native framework maintainers are pretty smart—`HotwireTabBarController` already does exactly that! So we can use it directly.

```
// hotwire-native-
ios:Source/Turbo/ViewControllers/HotwireTabBarController.swift

import UIKit

/// A tab bar controller that manages multiple tabs, each associated with
```
