This technique of passing around a `NavigationHandler` reference is quite useful when building Hotwire Native apps. For example, when rendering a fully native screen, you can call `navigationHandler.route(someURL)` from a button tap—bridging the gap back to the Hotwire world to present a web-rendered screen.

Test the new and improved notification handling by running the app and locking the simulator again. Trigger a notification by unliking and then liking the Forest Park hike again. When the notification appears, tap it. A new screen gets pushed on the stack, showing the hike!

That's a wrap for push notifications on iOS. Up next, we'll add push notifications to the Android app.

If you're only developing for iOS, then skip ahead to *What's Next?*, to recap everything you've learned and think about how you can apply these lessons further out in the world.
