```
»                   "notification-token",
»                   ::NotificationTokenComponent
»               )
            )

            Hotwire.config.jsonConverter = KotlinXJsonConverter()
        }
    }
```

We're now requesting permission from the user and gathering the notification token. All that's left is to get the token to the server.

POST Firebase Token to Server

We'll POST the notification token to the server with a view model. Create a new file under the `viewmodels` package and name it `NotificationTokenViewModel`. Add a public function that accepts a `String`.

ch10_59/android/app/src/main/java/com/masilotti ...
journal/viewmodels/NotificationTokenViewModel.kt

```
package com.masilotti.hikingjournal.viewmodels

import kotlinx.coroutines.Dispatchers
import kotlinx.coroutines.withContext

class NotificationTokenViewModel {
    suspend fun registerToken(token: String) = withContext(Dispatchers.IO) {
    }
}
```

The `withContext(Dispatchers.IO)` at the end of this function lets it run on a background thread—perfect for making network requests. It will also leave our implementation a bit cleaner since we won't have to nest a `withContext()` block.

Next, create a `URL` and open a connection on it. Cast this result to a `HttpURLConnection` so we can set the HTTP method and grab the response
