

Our Android app can now register for and receive push notifications from our Rails server. All that's left is to handle what happens when the notification is tapped.

Route Android Notifications

We'll route the `path` from the notification payload, just as on iOS.

On Android, every notification provides a custom `Intent` to the app's main activity. Open `MainActivity` and pass the `Intent` to a new private function named `handleDeepLink(intent: Intent?)`.

Android Intents are like Rails controller actions combined with `redirect_to`. They're how Android apps launch activities or services and pass data between them. Think of them as structured messages that tell the system what you want to do (like open a screen or share content) and what data to include.

ch10_66/android/app/src/main/java/com/masilotti/hikingjournal/activities/MainActivity.kt

```
    package com.masilotti.hikingjournal.activities

» import android.content.Intent
  import android.os.Bundle
  import android.view.View
  import androidx.activity.enableEdgeToEdge
  // ...

  class MainActivity : HotwireActivity() {
      // ...
```
