Gradle[17] is similar to Bundler in Ruby but is much more powerful. It not only manages dependencies like a Gemfile but also handles tasks like compiling your app, packaging resources, running tests, and creating different build versions (for example, debug vs. release).

In this file, make sure that **compileSdk** and **targetSdk** are set to version 35. Without this, your app might fail to build.

ch01_11/android/app/build.gradle.kts

```
plugins {
    alias(libs.plugins.android.application)
    alias(libs.plugins.kotlin.android)
}

android {
    namespace = "com.masilotti.hikingjournal"
»   compileSdk = 35

    defaultConfig {
        applicationId = "com.masilotti.hikingjournal"
        minSdk = 28
»       targetSdk = 35
        versionCode = 1
        versionName = "1.0"

        testInstrumentationRunner = "androidx.test.runner.AndroidJUnitRunner"
    }

    // ...
}
```

Then, open **libs.versions.toml** and make sure Kotlin is set to 2.0.0 or later.

ch01_11/android/gradle/libs.versions.toml

```
[versions]
agp = "8.9.2"
» kotlin = "2.1.0"
coreKtx = "1.16.0"
junit = "4.13.2"
```
