```
        android:id="@+id/main"
        android:name="dev.hotwire.navigation.navigator.NavigatorHost"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        app:defaultNavHost="false" />
```

`android:id` identifies this node. We'll use this in code to locate the `SessionNavHostFragment`.

`android:name` is the name of the fragment contained in this view. The value of this property comes from Hotwire Native, hence the `dev.hotwire.navigation` package prefix.

`android:layout_width` and `android:layout_height` tell the view how much space it should take up. We set both values to `match_parent` to fill the screen.

OK, the view layout is set up to render the Hotwire Native fragment. The next step is telling the app to use this layout and configuring Hotwire Native.

Update the Activity

An Android *activity* is an entry point to the application—it provides a window for a developer to lay out their UI elements and pass user interactions back to code. While complex apps can have multiple activities, we'll stick to a single one.

Expand `app`, `kotlin+java`, and then `com.masilotti.hikingjournal`, and double-click `MainActivity` to open it.
