Routing Modals

To remedy the issue with the form, you can use a *modal* to break context and encourage a distinct, narrowly scoped task. With mobile apps, modals are screens that are presented from the bottom—they don't slide in from the side, which is a traditional mobile navigation action. This distinction helps the user differentiate between two workflows.

Here are a couple of example modals, iOS on the left and Android on the right, from the Hotwire Native demo apps.

Hotwire Native supports a few navigation options out of the box, modals being one of them. This chapter will cover how to effectively use modals and other navigation techniques to create a better user experience in your apps—one that more closely resembles how users expect native apps to behave.
