Remember, a big benefit of Hotwire Native is that it keeps your business logic in one place: the Rails server. We don’t want to hardcode into the apps which screens get presented as modals—that detail should come from the server. Instead, you wire up rules that map different URL paths to different navigation patterns. And you do this via *path configuration*.

Path configuration is represented as a JSON file hosted on the server. Based on the settings you configure for this JSON file, your native apps can change their behavior. You’ll use path configuration to tell your apps how to present different screens. And because the JSON file lives on the server, not in the app, you’re free to update this file in between releases to the app stores to skip the review process.

For each platform, you’ll first set up the path configuration. Then, you’ll wire up the clients. Ready? Let’s dive in.
