Set Up iOS Path Configuration

To set up iOS path configuration, first create a new route (or endpoint) on the server that points to `/configurations/ios_v1`.

ch03_01/rails/config/routes.rb

```
    Rails.application.routes.draw do
      resource :session, only: %i[new create destroy]

      resources :hikes do
        resource :map, only: :show
        resources :likes, only: %w[create destroy]
      end

      resources :users, only: :index do
        resources :hikes, only: :index, controller: :user_hikes
      end

»     resources :configurations, only: [] do
»       get :ios_v1, on: :collection
»     end

      root "hikes#index"
    end
```

You'll want different path configurations for each platform, so prefix this one with `ios`. I also like to version the resource just in case a future version of the app introduces a breaking change, hence the `v1`.

Next, create a new Rails controller that maps to this route. For now, respond with an empty JSON object.

ch03_02/rails/app/controllers/configurations_controller.rb

```
» class ConfigurationsController < ApplicationController
»   def ios_v1
»     render json: {
»     }
```
