

Zenithal Projections

Oblique zenithal: when the plane is tangent to a point between a pole and the equator.

Polar zenithal: when the plane is tangent to one of the poles.

According to properties, map projections can be classified as:

Equal area projection: It is also known as homolographic projections. The areas of different parts of earth are correctly represented by such projections.

True shape projection: It is also known as orthomorphic projections. The shapes of different parts of earth are correctly represented on these projections.

True scale or equidistant projections: Projections that maintain correct scale are called true scale projections. However, no projection can maintain the correct scale throughout. Correct scale can only be maintained along some parallels or meridians.

Classification based on Position of light source

Placing light source illuminating the globe at different positions results in the development of different projections. These projections are

Gnomonic projection: when the source of light is placed at the centre of the globe

Stereographic Projection: when the source of light is placed at the periphery of the globe, diametrically opposite to the point at which developable surface touches the globe.

Orthographic Projection: when the source of light is placed at infinity from the globe opposite to the point at which developable surface touches the globe.
