Cylindrical Equi –Distant Projection

This is a Projection on to a cylinder which is tangent to the equator. It is believed to be invented by Marinus of Tyre, about C.E. 100.

Properties of Cylindrical Equi-Distant Projection

- Poles are straight lines equal in length to the equator.
- Meridians are straight parallel lines, equally spaced and are half as long as the equator. All meridians are of same length therefore scale is true along all meridians
- Parallels are straight, equally spaced lines which are perpendicular to the meridians and are equal to the length of the equator.
- Length of the equator on the map is the same as that on the globe but the length of other parallels on map is more than the length of corresponding parallels on the globe. So the scale is true only along the Equator and not along other parallels.
- Distance between the parallels and meridians remain same throughout the map.
- Since the projection is neither equal area nor orthomorphic, maps on this projection are used for general purposes only.

Example 10.2

Construct a cylindrical equi-distant projection for the whole globe with a reduced earth radius of 2 cm and the latitudinal and longitudinal interval 30°.
