After you have finished filling in the form, we can submit it and Twitter will show the dashboard for our newly-created application. In this screen, we must write down both **Consumer key** and **Consumer secret** values because we will use it later in our application configuration. Both keys are important in helping our application identify itself to Twitter.

Configuring OmniAuth for authentication using Twitter

After successfully registering our application in the Twitter developer website, we can now set up our application to enable remote authentication using Twitter. We will begin by specifying the **Consumer key** and **Consumer secret** values that we got earlier from Twitter at `config/initializers/devise.rb`. We specify the configuration at the Devise initializer instead of OmniAuth because Devise will be the bridge that connects OmniAuth and our application.
