In the example, I wrote a case where the user signs in with a Twitter account. So, what about a Facebook account? You can apply the same test with a Facebook account with minor changes. First, you should change the provider value in `request.env["omniauth.auth"]` from `twitter` to `facebook`. In every test case, you should replace `get :twitter` with `get :facebook`. This should do it and the test will be performed with Facebook as its provider.

Summary

In this chapter you have learned about how to test some of the Devise actions. Some of them are performed with the default Ruby on Rails testing tool and some use RSpec and Factory Girl. With different testing tools being used in the examples, you are expected to be able to compare which tool is more suitable for you. The test itself is meant to make your Devise and application more solid and less faulty. As I have said earlier, you may think that this activity will consume some of your time, which could be allocated to developing other features, or you can say that developers can perform the test manually. However, as the application grows, developers will start losing track of the bugs they have exterminated and tests they have performed. Repeating the same test manually will be more inefficient. The point is that depending on the size of your application, you may choose whether to apply the test or not, but the end point of the development should remain the same; that is, to develop a useful and solid application.
