DO YOU KNOW?

World Food Day – October 16

Classification of lipids

Lipids are classified into 4 categories as follows:

I. On the basis of chemical composition

II. On the basis of sources

Fats are divided into 2 types based on their source, namely **visible** and **invisible** fats.

III. On the basis of fatty acids

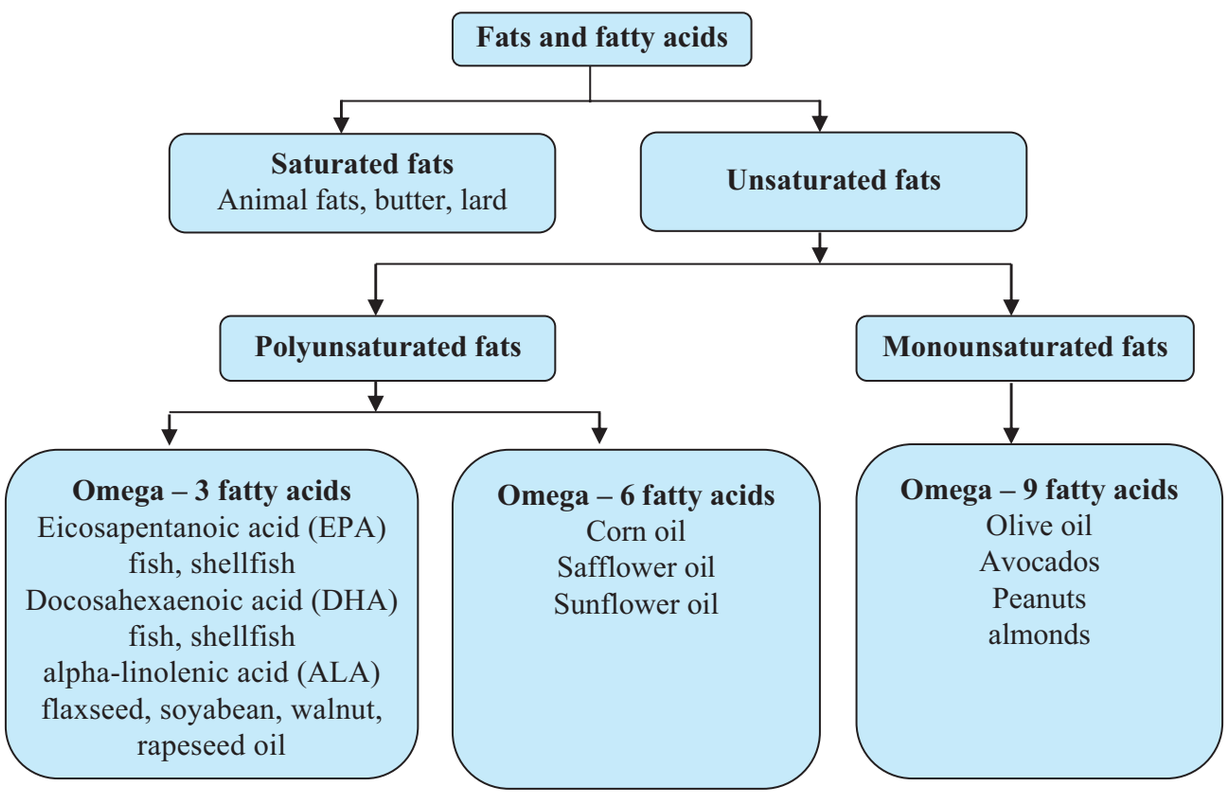

IV. On the basis of requirement

Fatty acids are of 2 types:

1. Essential fatty acids: Fatty acids which are essential to be taken in our diet because they cannot be synthesized in our body are known as essential fatty acids. (eg.) Linoleic, linolenic and arachidonic acids.
2. Non-essential fatty acids: Non-essential fatty acids are those which can be systhesized by the body and which need not be supplied through the diet. Palmitic acid, oleic acid and butyric acid are examples of non-essential fatty acids.

Digestion, absorption and storage metabolism

Fats are not digested in the stomach. Fats delay emptying of the stomach. Fats are hydrolyzed by the pancreatic and intestinal lipases in the intestines into diglycerides, monoglycerides and fatty acids. Bile is essential for the digestion and absorption of fats.
