other molecules into the urine from the blood after it is processed by the kidney.

The process of urine production

The entry of blood into the kidneys → filtration of blood → ultra filtration → Re absorption → Secretion → Excretion of urine

Kidney physiologically prompts the secretion of Antidiuretic hormone and Aldosterone and production of enzymes like Renin and Angiotensin II

NOTE: A normal adult human void from 800 to 2,000 ml of urine per day. Urinary output less than 800 mLs per day and less than 30 mLs per hour are considered oliguria; urinary output in excess of 2,000 ml per day is considered polyuria; and the absence of all urine production is referred to as anuria.

Functions of the urinary system

- Eliminates wastes from the body
- Manages and controls the homeostasis of the body in terms of its pH or acid-base balance
- Manages and controls the homeostasis of the body in terms of its electrolytes and electrolyte balance
- Manages and controls the blood pressure
- Stores urine until voiding is prompted
- Enables the process of urination
- Remove wastes like urea and ammonia from the blood
- Manage and control the fluids and fluid balance in the body by holding or retaining water and releasing and removing water from the blood stream
- Serve with endocrine functions such as the production of erythropoietin and calcitriol which are needed for the production of red blood cells and the reabsorption of calcium, respectively.

Disease related to urinary system

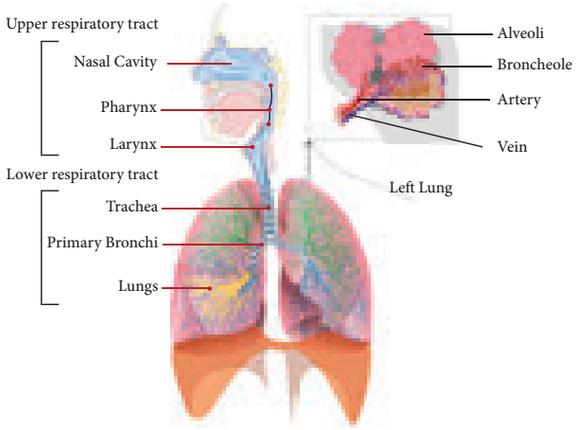

- Urinary tract infection
- Urolithiasis
- Nephrolithiasis
- Renal failure
- Renal cysts
- Glomerulonephritis
- Cancers of the urinary tract
- Dialysis

1.8 Respiratory system

Introduction

Respiratory system provides the body with oxygen required to sustain life and to eliminate carbon dioxide. The respiratory system works in association with the heart and lungs.

Air is breathed in through the nose or the mouth. In nasal cavity, a layer of mucus membrane acts as a filter and traps pollutants and other harmful substances found in the air. Next air moves in to the pharynx, a passage that contains the intersection between the oesophagus and the larynx. The opening of the larynx has a special flap of cortilage the epiglottis that opens to allow air to pass through but closes to prevent food from moving in to the airway.

Respiratory System
