- Major functions are to accept a fertilized ovum which becomes implanted into the endometrium, and menstruation.

The fallopian tube

The fallopian tubes are two tubes leading from the ovaries in to the uterus. They enable the passage of ovum from the ovaries to the uterus. Different segments are interstitial, isthmus, ampulla, infundibulum and fimbriae. Fertilization takes place in the ampulla of the fallopian tube.

Ovaries

The ovaries are considered as the female gonade. Each ovary is whitish in colour and located alongside the lateral wall of the uterus. It secretes estrogen, testosterone, Inhibin and progesterone. These hormones are responsible to maintain menstrual cycle, pregnancy and development of breast.

Functions of the female reproductive system

- To produce ovum.
- To protect and nourish fertilized egg until it is fully developed.
- To give birth.
- Menstruation.
- To have sexual intercourse.

Diseases related female reproductive system

- Breast cancer
- Cervical cancer
- Ovarian cancer
- Poly cystic ovarian disorder
- Menorrhagia
- Fibroids

Male Reproductive System

The male reproductive system consists of internal and external organs.

The external organs

- Penis
- Scrotum

The Penis

The tip of the penis is protected with foreskin. The penis enlarges and becomes erect with sexual excitation because there is a rich supply of blood.

The Scrotum

The scrotum lies bilaterally behind the penis. The scrotal sac holds and protects the testes.

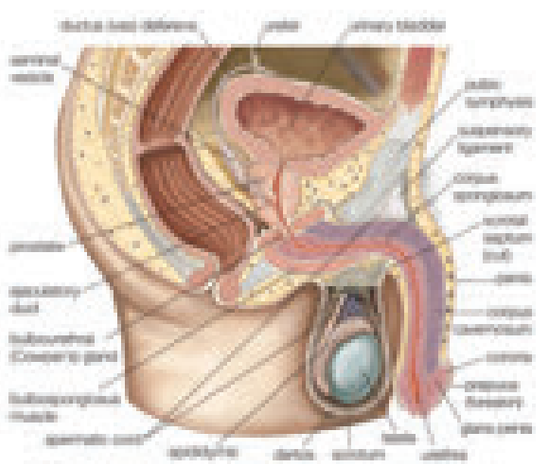

NOTE: The scrotum moves upward and downward when it is exposed to cold and warm environmental temperatures, respectively.

The internal organs are the

- Testes
- Vas deferens
- Ejaculatory ducts
- Urethra
- Epididymis
- Seminal vesicles
- Prostate gland

Testes

The testicles, or testes, lie bilaterally to the penis in the scrotum. The testes are endocrine glands and gonads.
