2. Serous pericardium- double layer of serous membrane.

The Fibrous Pericardium continues with the tunica adventitia of the great blood vessels above and is adherent to the diaphragm. It consists of two layers.

- The outer layer of the serous pericardium is the parietal pericardium
- The inner layer is visceral pericardium adherent to the heart muscles.

It secretes serous fluid called pericardial fluid. Pericardial fluid present in the space between the visceral and parietal layer, which allow smooth movement of the heart.

Myocardium

The myocardium is composed of specialized cardiac muscles found only in the heart. The Muscle arrangement of the myocardium enable the atria and ventricles to contract in a coordinated and efficient manner. It is also important for electrical activity of the heart.

Endocardium

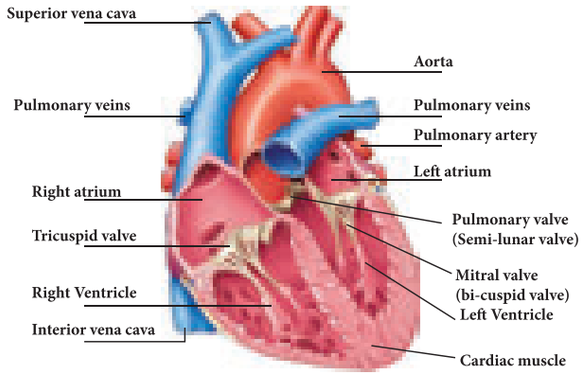

It lines chambers and valves of the heart. It is a thin, smooth membrane to ensure smooth flow of blood through the heart. It consists of flattened epithelial cells, and it is continuous with the endothelium lining of blood vessels.

The cardiovascular [cardio-heart, vascular-blood vessels] system is divided for descriptive purpose into two main parts.

1. The heart pumping action ensures constant circulation of the blood.
2. The blood vessels which form a lengthy network through which the blood flows.

The lymphatic system is closely connected by both structurally and functionally with a cardiovascular system.

The heart pumps blood in to three anatomically separate systems of blood vessels.

Heart

- The pulmonary circulation
- The systemic circulation
- The coronary circulation.

Pulmonary Circulation

The portion of the circulatory system which carries deoxygenated blood away from the right ventricle of the heart, to the lungs and returns oxygenated blood to the left atrium and ventricle of the heart.

Systemic Circulation

Systemic circulation carries oxygenated blood from the left ventricle, through the arteries to the capillaries in the tissues of the body. From the tissue capillaries the deoxygenated blood returns through a system of veins to the right atrium of the heart.

Coronary Circulation

Coronary Circulation is the circulation of blood in the blood vessels that supplies the heart muscles.

The cardiovascular system ensures a continuous flow of blood to all body cells. Heart plays a major role in continual physiological adjustment to maintain an adequate blood supply.

Interior of the heart

The heart is divided into a right and left side by the septum, partition consisting
