GoI, through NEGVAC, facilitate the import of these, but also placed an advance order worth ₹1,500 crore with the company which would be adjusted later on delivery of the doses in order to provide them critical financial assistance to purchase the required raw materials. Following the initial ₹25 crore of seed fund, Gennova, which was manufacturing India's first mRNA vaccine, was provided over ₹100 crore to further upgrade facilities, purchase raw material and conduct Phase III trials.

As soon as the vaccines became available, NEGVAC began to simultaneously plan the logistics of their equitable and correct distribution, with minimal wastage. Innovative technologies and digital trackers would have to be used while relying on some of our tried-and-tested measures of vaccine distribution. eVIN portal, an indigenously developed technology system which was capable of digitizing vaccine stocks and monitoring the temperature of the cold chain through a smartphone application, was planned to be upgraded and repurposed. eVIN was already being used in 12 states and was created in order to support the GoI's Universal Immunization Programme by providing real-time information on vaccine stocks and storage temperatures. Cold chain handlers were provided eVIN-enabled smartphones which would allow for digitization of vaccine inventories when they would enter net utilization for each vaccine at the end of every immunization day. These entries would simultaneously be uploaded on a cloud server to which programme managers at district, state and national levels had access to via an online dashboard which they could further use to replenish diminishing stocks. In addition, SIM-enabled loggers could be attached to cold chain equipment with capacities to capture temperature information through digital sensors placed in the refrigerators every 10 minutes. In case of a temperature breach, the logger alarms would send SMS and email alerts to the respective managers and technicians, inciting a quick response, thus saving vaccines from going bad. Over 17,000 people were already trained to use the eVIN technology, which meant that it could be scaled up easily and rather quickly.[7] It was e-VIN which would later become CoWIN after significant technological interventions with user interfaces. In line with the prime minister's directions in June 2020, CoWIN was conceived to satisfy a need for a digital health ID to ensure that no Indian got left out from the vaccination process. They concurred that management of such a technological backbone would have to be handled by a separate expert team outside of NEGVAC.
